Solution Review: Problem Challenge 2

We'll cover the following

Maximum CPU Load (hard)

We are given a list of Jobs. Each job has a Start time, an End time, and a CPU load when it is running. Our goal is to find the **maximum CPU load** at any time if all the **jobs are running on the same machine**.

Example 1:

```
Jobs: [[1,4,3], [2,5,4], [7,9,6]]
Output: 7
Explanation: Since [1,4,3] and [2,5,4] overlap, their maximum CPU load (3+4=7) wil
l be when both the
jobs are running at the same time i.e., during the time interval (2,4).
```

Example 2:

```
Jobs: [[6,7,10], [2,4,11], [8,12,15]]
Output: 15
Explanation: None of the jobs overlap, therefore we will take the maximum load of
 any job which is 15.
```

Example 3:

```
Jobs: [[1,4,2], [2,4,1], [3,6,5]]
Output: 8
Explanation: Maximum CPU load will be 8 as all jobs overlap during the time interv
al [3,4].
```

Solution

The problem follows the Merge Intervals (https://www.educative.io/collection/page/5668639101419520/5671464854355968/5652017242439680/) pattern and can easily be converted to Minimum Meeting Rooms (https://www.educative.io/collection/page/5668639101419520/5671464854355968/5710239819104256/). Similar to 'Minimum Meeting Rooms' where we were trying to find the maximum number of meetings happening at any time, for 'Maximum CPU Load' we need to find the

maximum number of jobs running at any time. We will need to keep a running count of the maximum CPU load at any time to find the overall maximum load.

Code

Here is what our algorithm will look like:

Java | Python3 | C++ | JS

```
from heapq import *

class job:
  def __init__(self, start, end, cpu_load):
    self.start = start
    self.end = end
    self.cpu_load = cpu_load

  def __lt__(self, other):
    # min heap based on job.end
    return self.end < other.end

def find_max_cpu_load(jobs):
  # sort the jobs by start time
  jobs.sort(key=lambda x: x.start)
  max_cpu_load, current_cpu_load = 0, 0
  min_heap = []

  for j in jobs:
    # remove all the jobs that have ended
    while(len(min_heap) > 0 and j.start >= min_heap[0].end):
      current_cpu_load -= min_heap[0].cpu_load
      heappop(min_heap)
    # add the current job into min_heap
    heappush(min_heap, j)
    current_cpu_load += j.cpu_load
```

Time complexity

The time complexity of the above algorithm is $O(N * logN)$, where 'N' is the total number of jobs. This is due to the sorting that we did in the beginning. Also, while iterating the jobs, we might need to poll/offer jobs to the priority queue. Each of these operations can take $O(logN)$. Overall our algorithm will take $O(NlogN)$.

Space complexity

The space complexity of the above algorithm will be $O(N)$, which is required for sorting. Also, in the worst case, we have to insert all the jobs into the priority queue (when all jobs overlap) which will also take $O(N)$ space. The overall space complexity of our algorithm is $O(N)$.
