

Implementing a Binary Search Tree in Python

In this lesson, we'll implement a very basic Binary Search Tree in Python

We'll cover the following

- Introduction
 - The Node Class
 - The BinarySearchTree class
 - Putting the two together

Introduction

The Node Class

To implement a BST, the first thing you'd need is a node. A node should have a value, a left child, a right child, and a parent. This node can be implemented as a Python class and here is the code.

 Node.py

```
1 class Node:
2     def __init__(self, val): # Constructor to initialize the value of the node
3         self.val = val
4         self.leftChild = None # Sets the left and right children to `None`
5         self.rightChild = None
6         self.parent = None # Sets the parent to `None`
7
```

The BinarySearchTree class

You can then choose to create a wrapper class for the tree itself; this can sometimes make your code cleaner and easier to read, but not always. However, this is a programming convention so let's create a tree class:

 BinarySearchTree.py

```
1 class BinarySearchTree:
2     def __init__(self, val): # Initializes a root node
3         self.root = Node(val)
4
```

Putting the two together

When both classes are put together, you get a BST. Let's try running this.

BinarySearchTree.py

Node.py

```
1 from Node import Node # use `Node` class from Node.py
2
3
4 class BinarySearchTree:
5     def __init__(self, val): # Initializes a root node
6         self.root = Node(val)
7
8
9 BST = BinarySearchTree(6) # Initializes a BST
10 print(BST.root.val) # print value of root node
11
```

Output

6

0.495s

Now that we have some bare bones code for binary search trees, let's look at a high-level algorithm and code to insert values into a BST!
