

Unique Generalized Abbreviations (hard)

We'll cover the following ^

- Problem Statement
- Try it yourself
- Solution
- Code
 - Time complexity
 - Space complexity
- Recursive Solution

Problem Statement

Given a word, write a function to generate all of its unique generalized abbreviations.

Generalized abbreviation of a word can be generated by replacing each substring of the word **by the count of characters in the substring**. Take the example of “ab” which has four substrings: “”, “a”, “b”, and “ab”. After replacing these substrings in the actual word by the count of characters we get all the generalized abbreviations: “ab”, “1b”, “a1”, and “2”.

Example 1:

Input: "BAT"
Output: "BAT", "BA1", "B1T", "B2", "1AT", "1A1", "2T", "3"

Example 2:

Input: "code"
Output: "code", "cod1", "co1e", "co2", "c1de", "c1d1", "c2e", "c3", "1ode", "1od1",
"1o1e", "1o2",
"2de", "2d1", "3e", "4"

Try it yourself

Try solving this question here:

 Java

 Python3

 JS

 C++

```
1 def generate_generalized_abbreviation(word):
2     result = []
3     # TODO: Write your code here
4     return result
5
```

```

6
7 def main():
8     print("Generalized abbreviation are: " +
9           str(generate_generalized_abbreviation("BAT")))
10    print("Generalized abbreviation are: " +
11          str(generate_generalized_abbreviation("code")))
12
13
14    main()
15

```

Solution

This problem follows the Subsets

(<https://www.educative.io/collection/page/5668639101419520/5671464854355968/5670249378611200>) pattern and can be mapped to Balanced Parentheses

(<https://www.educative.io/collection/page/5668639101419520/5671464854355968/5753264117121024/>). We can follow a similar BFS approach.

Let's take Example-1 mentioned above to generate all unique generalized abbreviations.

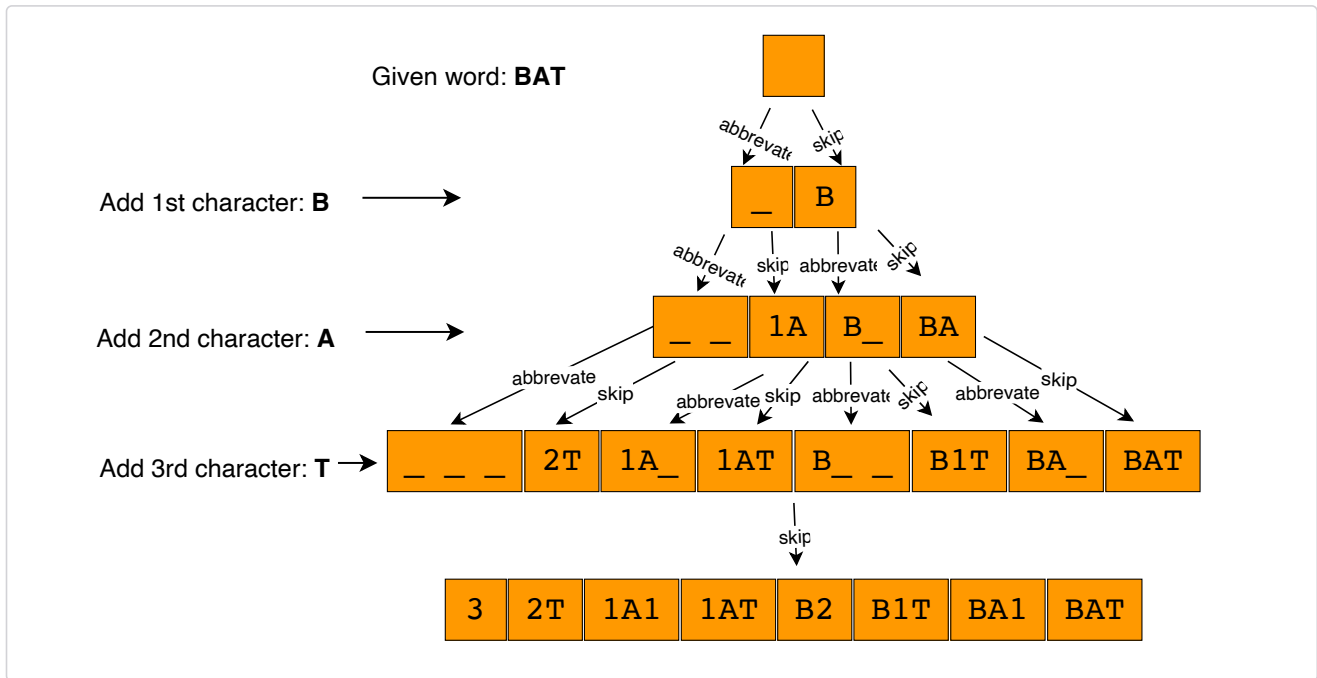

Following a BFS approach, we will abbreviate one character at a time. At each step we have two options:

- Abbreviate the current character, or
- Add the current character to the output and skip abbreviation.

Following these two rules, let's abbreviate BAT :

1. Start with an empty word: ""
2. At every step, we will take all the combinations from the previous step and apply the two abbreviation rules to the next character.
3. Take the empty word from the previous step and add the first character to it. We can either abbreviate the character or add it (by skipping abbreviation). This gives us two new words: _ , B .
4. In the next iteration, let's add the second character. Applying the two rules on _ will give us _ _ and 1A . Applying the above rules to the other combination B gives us B_ and BA .
5. The next iteration will give us: _ _ _ , 2T , 1A_ , 1AT , B _ _ , B1T , BA_ , BAT
6. The final iteration will give us: 3 , 2T , 1A1 , 1AT , B2 , B1T , BA1 , BAT

Here is the visual representation of this algorithm:

Code

Here is what our algorithm will look like:

 Java
  Python3
  C++
  JS

```

1  from collections import deque
2
3
4  class AbbreviatedWord:
5
6      def __init__(self, str, start, count):
7          self.str = str
8          self.start = start
9          self.count = count
10
11
12  def generate_generalized_abbreviation(word):
13      wordLen = len(word)
14      result = []
15      queue = deque()
16      queue.append(AbbreviatedWord(list(), 0, 0))
17      while queue:
18          abWord = queue.popleft()
19          if abWord.start == wordLen:
20              if abWord.count != 0:
21                  abWord.str.append(str(abWord.count))
22                  result.append(''.join(abWord.str))
23              else:
24                  # continue abbreviating by incrementing the current abbreviation count
25                  queue.append(AbbreviatedWord(list(abWord.str),
26                                                  abWord.start + 1, abWord.count + 1))
27
28          # restart abbreviating, append the count and the current character to the string

```

educative

Since we had two options for each character, we will have a maximum of 2^N combinations. If you see the visual representation of Example-1 closely you will realize that it is equivalent to a binary tree, where each node has two children. This means that we will have 2^N leaf nodes and $2^N - 1$ intermediate nodes, so the total number of elements pushed to the queue will be $2^N + 2^N - 1$, which is asymptotically equivalent to $O(2^N)$. While processing each element, we do need to concatenate the current string with a character. This operation will take $O(N)$, so the overall time complexity of our algorithm will be $O(N * 2^N)$.

Space complexity

All the additional space used by our algorithm is for the output list. Since we can't have more than $O(2^N)$ combinations, the space complexity of our algorithm is $O(N * 2^N)$.

Recursive Solution

Here is the recursive algorithm following a similar approach:

Java

Python3

C++

JS JS

```

1 def generate_generalized_abbreviation(word):
2     result = []
3     generate_abbreviation_recursive(word, list(), 0, 0, result)
4     return result
5
6
7 def generate_abbreviation_recursive(word, abWord, start, count, result):
8
9     if start == len(word):
10         if count != 0:
11             abWord.append(str(count))
12             result.append(''.join(abWord))
13     else:
14         # continue abbreviating by incrementing the current abbreviation count
15         generate_abbreviation_recursive(
16             word, list(abWord), start + 1, count + 1, result)
17
18         # restart abbreviating, append the count and the current character to the string
19         if count != 0:
20             abWord.append(str(count))
21         newWord = list(abWord)
22         newWord.append(word[start])
23         generate_abbreviation_recursive(word, newWord, start + 1, 0, result)
24
25
26 def main():
27     print("Generalized abbreviation are: " +
28         str(generate_generalized_abbreviation("BAT")))

```
