

# Overview of Iterative Functions

In this lesson, we will learn about Iteration.

We'll cover the following

- What is Iteration?
- Format of an Iterative Function
  - Syntax of an Iterative Function
  - Calculating Factorial of a Number

## What is Iteration? #

Iteration means repeating some steps to achieve the desired outcome. In computer programming, iteration processes usually involve a mechanism, including **loops**.

As we learn about recursion, it is also important to have an overview of iteration.

## Format of an Iterative Function #

Each iterative function consists of a loop and a conditional statement that determines whether to continue iteration or to stop further execution.

Code flow of an iterative function

In the illustration above, the dotted line encapsulates the **iterative** part of the code flow.

## Syntax of an Iterative Function #

Let's take a look at how to code an iterative function using python:

```
def IterativeFunction() :  
    <some local variables if required>  
    while <someCondition == TRUE> :  
        # Perform a task
```

## Calculating Factorial of a Number #

Let's take a look at the iterative code for calculating the factorial of a specific number. Review the recursive code for this function in our previous lesson

(<https://www.educative.io/collection/page/6151088528949248/4547996664463360/6091301726453760>).

Iterative

Recursive

```
1  def factorial(targetNumber) :  
2      # Base case  
3      if targetNumber == 1 : # Factorial of 1 is 1  
4          return 1  
5  
6      # Recursive case  
7      else :  
8          return (targetNumber * factorial(targetNumber - 1))  
9  
10 # Driver Code  
11 targetNumber = 5  
12 result = factorial(targetNumber)  
13 print("The factorial of " + str(targetNumber) + " is: " + str(result))
```

Recursive method for calculating factorial of a number

For the **iterative** version of this function, we initiate a simple `while` loop and multiply `targetNumber` with `index` in each iteration. `index` is reduced by 1 in each iteration. This step is important because otherwise the program will be stuck in an infinite loop. The initial value of `index` is `targetNumber - 1`. Let's dry run this code by **keeping track of its variables**.

```
targetNumber = 5
```

```
index = 4
```

Initiating Loop

Start loop

1 of 6

condition  $\text{index} \geq 1$  is satisfied

Update targetNumber and subtract 1 from index

```
targetNumber = 20
```

```
index = 3
```

Iteration 1

2 of 6

condition  $\text{index} \geq 1$  is satisfied

Update targetNumber and subtract 1 from index

```
targetNumber = 60
```

```
index = 2
```

Iteration 2

3 of 6

condition  $\text{index} \geq 1$  is satisfied

Update targetNumber and subtract 1 from index

```
targetNumber = 120
```

```
index = 1
```

Iteration 3

4 of 6

condition `index >= 1` is satisfied

Update `targetNumber` and subtract 1 from `index`

```
targetNumber = 120
```

```
index = 0
```

Iteration 3

5 of 6

condition `index >= 1` is not satisfied

Return `targetNumber`

```
targetNumber = 120
```

Return function

6 of 6

— [ ]

In the next lesson, we will highlight the major differences between iteration and recursion.
