Solution Review: Problem Challenge 1

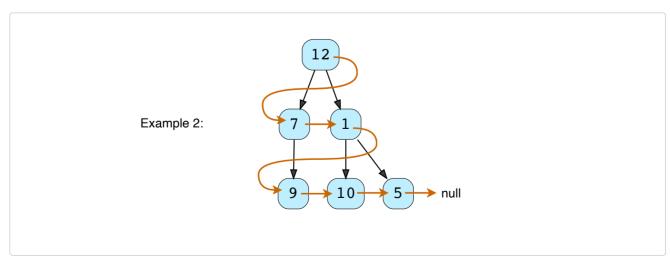

We'll cover the following

- Connect All Level Order Siblings (medium)
- Solution
- Code
 - Time complexity
 - Space complexity

Connect All Level Order Siblings (medium)

Given a binary tree, connect each node with its level order successor. The last node of each level should point to the first node of the next level.

Solution

\$

This problem follows the Binary Tree Level Order Traversal

(https://www.educative.io/collection/page/5668639101419520/5671464854355968/572660793946 9312/) pattern. We can follow the same **BFS** approach. The only difference will be that while traversing we will remember (irrespective of the level) the previous node to connect it with the current node.

Code

Here is what our algorithm will look like; only the highlighted lines have changed:

```
Python3
👙 Java
                         G C++
                                      Js JS
 1 from __future__ import print_function
 2 from collections import deque
 3
 4
 5
   class TreeNode:
 6
      def __init__(self, val):
 7
        self.val = val
 8
        self.left, self.right, self.next = None, None, None
 9
      # tree traversal using 'next' pointer
10
      def print_tree(self):
11
        print("Traversal using 'next' pointer: ", end='')
12
13
        current = self
14
        while current:
          print(str(current.val) + " ", end='')
15
16
          current = current.next
17
18
19 def connect_all_siblings(root):
20
      if root is None:
21
        return
22
23
      queue = deque()
24
      queue.append(root)
25
      currentNode, previousNode = None, None
26
      while queue:
27
        currentNode = queue.popleft()
28
        if previousNode:
                                                                                          \leftarrow
\triangleright
```

Time complexity

The time complexity of the above algorithm is O(N), where 'N' is the total number of nodes in the tree. This is due to the fact that we traverse each node once.

Space complexity

The space complexity of the above algorithm will be O(N) which is required for the queue. Since we can have a maximum of N/2 nodes at any level (this could happen only at the lowest level), therefore we will need O(N) space to store them in the queue.
